

Book 0: Doctrine

Cynqra Doctrine, v1.0. This book answers why Cynqra exists and what Cynqra is. It replaces the file "Cynqra Final PRD v1.0", which is now our historical first draft. This book changes rarely, and only by a founder decision recorded in Book 4.

Part I: Definition

1. What Cynqra is

Part I: Definition

1. What Cynqra is

Our locked definition:

Cynqra is a system that determines and executes the organizational changes required to move an organization from its current state toward a human

defined objective, using available intelligence, resources and evidence.

We say it in one sentence, three ways, depending on who asks:

- **For a founder:** tell Cynqra what you want to achieve. It builds the organization to pursue it, runs the organization, and changes it when reality demands it.
- **For an investor:** Cynqra is building a system for programmable organizations, where organizational structure can be created, operated and continuously changed around human objectives.
- **For the product team:** given an objective, current state, desired state, evidence, constraints and available resources, determine and execute the next organizational transition.

An organization managed by Cynqra can contain humans, AI workers, specialized intelligence, software systems, external services, money, compute, tools and data. The important question is never "human or artificial?" The important question is:

What capability is required, and what is the best way to provide that capability?

2. The problem

Today a founder has to build the organization before they can properly build the product. They personally find and coordinate every function: CTO, product, design, engineering, data, QA, marketing. They become the coordination layer for everything. We see seven specific problems:

1. The founder must build the organization before properly building the product.
2. Hiring the right people takes time.
3. Different workers have different strengths.
4. The organization becomes difficult to change.
5. Managers spend enormous amounts of time moving information between people.
6. The founder becomes the coordination layer for everything.
7. When reality changes, the organization does not automatically change with it.

3. The solution

We move the founder from managing people and tasks to defining objectives and controlling the decisions that genuinely need them.

4. The core loop

Everything in Cynqra exists to make one loop work reliably. This is the canonical diagram. Every other loop in this book is a view of this one.

- The **MVP proves the first transition**: human objective → organization → working product.
- The **long term Cynqra owns the complete loop**: objective → state → organizational transition → execution → evidence → next state.

Part II: Philosophy

5. Five principles

We hold five principles.

1. **Objective before organization.** We do not ask "which agents should we use?"
We ask "what are we trying to achieve?"
2. **Capability before worker.** We do not ask "which person should perform this?"
We ask "what capability is required?", then we find the best available source of that capability.
3. **Evidence before major change.** Cynqra does not change the organization because a system thinks something might be wrong. It gathers evidence whenever practical.
4. **Authority before action.** Not every decision can be made independently. The system must know what it is allowed to do.
5. **Reality determines evolution.** The organization changes because reality requires it, not because the system wants to create activity.

6. Three permanent capabilities

All of Cynqra reduces to three capabilities. Everything else is implementation.

- **Create**: determine and create the organization required for the objective.
- **Operate**: coordinate that organization to execute the work.
- **Adapt**: determine and execute the changes required when the organization no longer fits reality.

Part III: The Systems

7. Objectives

Objective System. Converts natural language into a structured objective. Input: *"Build a SaaS product that helps restaurants predict demand and optimize inventory."* Output: product definition, target customer, primary outcome, business outcome, success criteria, and constraints (budget, timeline, risk, technology, founder preferences).

Objective hierarchy. A company may hold multiple objectives (product, market, business). Cynqra must understand which objectives matter most.

Priorities. Every objective carries a priority: NON-NEGOTIABLE → HIGH → MEDIUM → OPTIONAL . Example: launch MVP within 90 days (primary), spend below \$50,000 (secondary), customer data security (non negotiable), advanced analytics (optional). Priorities let Cynqra make sensible tradeoffs.

Constraints define what Cynqra cannot freely violate: budget limits, time limits, security and legal requirements, data location, founder approval, risk tolerance, technology restrictions.

The decision space is therefore: OBJECTIVE + PRIORITIES + CONSTRAINTS + AUTHORITY → AVAILABLE DECISIONS .

Objective change. When the founder changes direction ("restaurants → hotels"), Cynqra does not overwrite the old objective. It runs impact analysis → affected work → affected workforce → preserve / stop / reassign → new objective → new organization.

8. State and knowledge

Company State. The most important representation of the company at a moment in time. Example: 17 customers, \$3,400 MRR, MVP product, team of 7, \$84,000 cash, 11 months runway. Product strong, engineering strong, customer acquisition weak. Primary constraint: distribution. The state changes continuously.

Company World Model. The broader knowledge Cynqra holds about the company: objective, product, market, customers, workforce, metrics, finance,

capabilities, risks, decisions, events, evidence. The World Model represents reality.

Company Genome. Answers *"what must be true for this objective to succeed?"* Required customer value → required product → required distribution → required economics → required capabilities → required organization. The Genome represents structural requirements.

The gap. Desired State minus Current State equals Gap. Cynqra continuously asks: what is preventing the current state from becoming the desired state? The difference between the Genome and the World Model produces the gap.

9. Capability and intelligence

Capability Engine. Cynqra never jumps from objective directly to worker. It first identifies required capabilities: product strategy, user research, UX, frontend, backend, data, infrastructure, security, testing, growth, operations.

Capability first architecture. Objective → required work → required capabilities → available intelligence → best fit → organization. This lets the underlying intelligence change without changing the organization.

Intelligence allocation. A required capability can come from a human, an AI worker, or a system. Cynqra evaluates capability fit, quality, reliability, cost, speed, availability, risk, and historical plus task specific performance.

Intelligence evaluation. Public benchmarks are not sufficient. We maintain our own evaluation system: standard evaluation → Cynqra task evaluation → trial work → real performance → performance record. Over time this answers: which intelligence works best for which type of work?

Model independence. Cynqra never depends permanently on one intelligence provider. The organization belongs to Cynqra. The underlying intelligence can change. If a provider fails: model failure → affected work → find alternative → evaluate → trial → verify → continue. If a new model version regresses on our evaluations, we block the update and keep the previous version.

10. Workforce

Worker. An organizational entity with identity, role, capabilities, responsibilities, memory, context, tools, permissions, authority, cost, availability, performance, current work, relationships, and history.

Worker identity remains stable even when the underlying intelligence changes: role + memory + history → current intelligence. We can replace the intelligence without destroying organizational continuity.

Workforce lifecycle. Required capability → candidates → evaluation → trial → hire → assign → execute → measure → performing? → continue, or review → improve / reassign → replace. This directly supports hire, assign, evaluate, replace.

11. Organization

Organization Synthesizer. Determines how capabilities are arranged: roles, responsibilities, ownership, dependencies, reporting, authority, communication, workstreams, teams.

An example organization Cynqra might synthesize:

Organizational Graph. The organization is machine readable. For anything in the company, Cynqra can answer: who owns this, who depends on this, who can approve this, who can change this, who reviews this, who can override this, who should be informed. The live graph spans people, workers, teams, roles, capabilities, tasks, dependencies, resources, decisions, authority, and objectives. It is one graph, one system.

Coordination. Workers operate as an organization, not as isolated conversations. Example: an engineer is blocked → the CTO investigates → discovers a missing product requirement → the CPO clarifies → the engineer continues. Dependencies resolve without unnecessarily involving the founder.

Organizational protocols. Coordination uses structured events: Request, Approval, Escalation, Blocker, Handoff, Review, Disagreement, Decision, Override, Failure, Reassignment. Every protocol event carries raised by, issue, severity, owner, required action, and status.

Disagreement. Cynqra does not choose at random. Disagreement → identify claims → collect evidence → assess authority → attempt resolution → escalate if required → founder decision.

12. Authority and risk

Authority system. Every worker has explicit authority. An engineer can write code, create branches, run tests, and open pull requests. That engineer cannot deploy production, change budget, change the objective, hire workforce, or change strategy. Authority is based on role, risk, decision type, delegation, performance, and founder policy.

Risk and reversibility. Not every action deserves the same level of approval. LOW risk: the worker executes. MEDIUM: manager review. HIGH: founder approval. We assess financial, business, security, legal, and customer impact, plus reversibility.

13. Execution

Execution Engine. Every task has objective, owner, context, inputs, expected output, dependencies, tools, budget, deadline, verification method, authority, and status. Task flow: **CREATED → PLANNED → ASSIGNED → READY → IN PROGRESS → REVIEW → VERIFIED → COMPLETED**.

Failure flow. Task failure → identify → classify → diagnose → remedy → retry → verify → learn. Repeated failures affect worker performance records, capability evaluation, planning, future workforce selection, and organization design.

Verification Engine. Cynqra distinguishes *task completed* from *task actually correct*. By risk: LOW → automated checks. MEDIUM → independent review. HIGH → human approval. Verified → complete. Not verified → rework.

14. Evidence and learning

Evidence Engine. Cynqra knows why it believes something: claim → source → evidence → confidence → interpretation → decision. Evidence comes from

company systems, analytics, customer feedback, worker observations, founder input, experiments, financial data, product usage, and external information.

Fact and belief separation. Cynqra distinguishes FACT, OBSERVATION, ASSUMPTION, HYPOTHESIS, PREDICTION, DECISION. Example: *17 customers exist* (fact) → *new users often abandon onboarding* (observation) → *onboarding complexity causes conversion loss* (hypothesis) → *test simplified onboarding* (experiment) → *increase investment if it succeeds* (decision).

Experiment Engine. Assumption → hypothesis → experiment → intervention → measurement → result → belief update. Experiments reduce uncertainty before large changes.

Organizational Transition Engine. The central long term intelligence. It compares current state + desired state + evidence + constraints + available resources, and determines what organizational transition should happen next: hire, fire, replace, reassign, create team, remove team, change responsibility, change budget, acquire capability, change strategy, run experiment, or do nothing.

Transition flow. Current state → gap → cause analysis → possible transitions → cost → risk → expected outcome → reversibility → recommendation → authority check → approval → execution → new state.

Transition record. Every significant transition creates a permanent record: company, problem, evidence, proposed change, expected result, cost, risk, approval, actual result, confidence. Over time this becomes extremely valuable.

Causal learning. Cynqra does not conclude that because revenue rose after a workforce change, the change caused it. It weighs intervention, expected effect, observed change, other changes, external factors, and confidence. The goal is not perfect scientific certainty. The goal is disciplined organizational learning.

Change management and rollback. Change proposed → impact analysis → dependency analysis → cost → risk → authority → approval → rollout → monitor → rollback if required. Where possible, significant changes are reversible: code, infrastructure, workforce, budget, configuration, organization.

15. Company evolution

Company state machine. Companies move through states: **IDEA → VALIDATION → MVP → PILOT → PRODUCT MARKET FIT → GROWTH → SCALE**. The process is not always linear: **GROWTH →**

PROBLEM → PIVOT → VALIDATION. Cynqra must understand the current stage because organizational requirements change with it.

Evolution loop. Company state → reality → evidence → organizational review → fitting (continue) or not fitting (transition → new organization → execution).

16. The founder

Founder approval. The founder remains the principal. The founder controls objective, budget, strategy, risk tolerance, major organizational changes, major financial decisions, major product decisions, and authority boundaries. Cynqra minimizes unnecessary founder involvement. It does not eliminate the founder.

Founder intervention metric. One of our core metrics: how much unnecessary coordination does Cynqra remove from the founder? Example trajectory: 42 interventions in month 1 → 18 in month 6 → 9 in month 12. The goal is not zero. The goal is that the founder spends time on the decisions that genuinely require their judgment.

17. Memory and history

Company Memory. The history of the organization: objectives, decisions, tasks, workers, performance, customer feedback, experiments, failures, successes, product changes, organizational changes, resources, outcomes.

Event System. Every meaningful change becomes a permanent event record: company created, objective created or changed, worker hired, assigned, reassigned, replaced, task created, blocked, failed, completed, verified, decision created, approved, rejected, budget changed, product released, customer feedback received, experiment created or completed, organization changed.

Company versioning. States are historically preserved (state 01 → 02 → 03 → 04). Cynqra can answer: what changed, why did it change, who approved it, what happened afterward.

18. Economics

Company economics. Cynqra understands the cost of the organization: workforce + models + tools + infrastructure + humans + time → total organizational cost. Then: expected outcome → expected value → cost →

expected return. Cynqra eventually optimizes not only for quality but for economic efficiency.

Resource allocation. The organization is larger than its workforce. Cynqra allocates people, AI workers, models, money, time, compute, tools, data, and external services. The question: what combination of resources gives the best probability of achieving the objective within constraints?

19. The external world

Cynqra does not remain isolated. A real company interacts with customers, suppliers, banks, cloud providers, marketplaces, email, CRM, accounting, legal services, analytics, human employees, and contractors. The system spans an internal world (workforce, tasks, decisions, resources) and an external world (customers, suppliers, services, platforms).

Humans and artificial workers are members of the same organizational system. They differ in capability, authority, cost, and execution method.

Context system. Workers do not receive everything. Context is layered: company → team → role → task → relevant memory → worker. Enough context for good decisions, without unnecessary complexity and cost.

20. Trust

Security. Every action has identity, permission, authority, context, and an audit record.

Auditability. For every important action, Cynqra can answer: who acted, what did they know, what authority did they have, which intelligence was used, what context was provided, what action was taken, what tools were used, what happened afterward.

Replay. If something goes wrong, the system allows reconstruction: company state → decision → context → intelligence → action → tool → result.

Data ownership. The founder owns the company: its knowledge, code, documents, designs, customer information, decisions, history, and organizational configuration.

Portability. A company built on Cynqra is never trapped in Cynqra. The founder can export code, data, documents, designs, company knowledge, decision history, organizational configuration, and infrastructure configuration. This creates trust.

Part IV: Product Experience

21. Interface

The founder interface is simple. The product does not feel like a collection of chat windows. Primary navigation:

Section	Contains
Company	Current state and overall health
Organization	People, intelligence and capabilities
Work	Projects, tasks and progress
Decisions	Important choices and approvals
Evolution	Proposed organizational changes

22. The four dashboards

- **Company dashboard:** objective, current state (customers, MRR, product stage, runway), organization summary, current constraint, pending decisions, active work with progress, and the current Cynqra recommendation with a Review action.
- **Organization dashboard:** the org graph as an interactive tree. Selecting a worker shows identity, role, capabilities, current work, performance, reliability, cost, authority, and history.
- **Decision dashboard:** each decision shows problem, evidence, recommendation, expected cost, risk, and confidence, with Approve / Reject / Request More Evidence.
- **Evolution dashboard:** organizational reviews. Current org, observation, constraint, recommended change, expected impact, status (for example, awaiting founder approval).

Part V: System Architecture

23. Architecture overview

UI → Control Plane → Objective System, Company System, Organization System → Orchestrator → Planning Engine, Workforce Engine, Decision Engine → Task Engine → Worker Runtime → Models, Tools, Memory → Action → Verification → Event System → Company World Model → Transition Engine → loop

24. Technology domains

- **Foundation:** authentication, users, companies, projects, permissions, billing, APIs, database, audit, events.
- **Company intelligence:** objective, genome, state, world model, evidence, assumptions, experiments, decisions.
- **Organization:** roles, capabilities, workers, teams, authority, relationships, dependencies, performance.
- **Execution:** tasks, planning, scheduling, dependencies, worker runtime, tool execution, verification.
- **Intelligence:** model registry, capability registry, evaluation, routing, performance, fallback.
- **Governance:** permissions, approval, budget, risk, audit, security.

25. Core data model

The backbone chain: OBJECTIVE → DESIRED STATE → CURRENT STATE → GAP → CAPABILITY → ORGANIZATION → WORKER → TASK → ACTION → OUTCOME → EVIDENCE → TRANSITION → NEW STATE .

Core entities: Founder, Company, Objective, DesiredState, CompanyState, CompanyGenome, Evidence, Assumption, Hypothesis, Experiment, Capability, IntelligenceSource, Worker, Organization, Role, Team, Task, Decision, Transition, Resource, Constraint, Permission, Event, Outcome.

Core event model: company.created, objective.created, objective.changed, state.changed, worker.hired, worker.assigned, worker.reassigned, worker.replaced, task.created, task.started, task.blocked, task.failed, task.completed, task.verified, decision.created, decision.approved, decision.rejected, experiment.created, experiment.completed,

budget.changed, organization.changed, transition.proposed, transition.approved,
transition.executed, outcome.recorded .

Exact schemas and contracts live in Book 2. This book defines the concepts. Book 2 defines the fields.

Part VI: The Execution Path

26. The MVP proof

The first product is much smaller than the vision. It proves exactly one thing:

A founder can describe a software product, and Cynqra can create and coordinate the organization required to produce a real working product.

The first version does **not**: run every type of company, replace every human, automate every business decision, build a universal intelligence marketplace, predict the future perfectly, autonomously reorganize without authority, handle every legal process, or operate every external system.

The first proof is execution. The full MVP specification (scope, acceptance criteria, metrics, journeys) lives in Book 1.

27. The roadmap

1. **Create.** Founder objective → working organization → working product.
2. **Operate.** Cynqra manages the workforce: work → performance → coordination → reassignment → replacement → improved execution.
3. **Understand.** Cynqra develops a reliable Company State: events → history → evidence → company memory → world model → current state.
4. **Decide.** Cynqra recommends what should happen next. The founder approves.
5. **Adapt.** Cynqra changes the organization: reality → evidence → gap → transition → approval → change → execution.
6. **Organizational intelligence.** Cynqra learns from accumulated transitions: company → decision → intervention → outcome → evidence → learning →

better future decisions. This is where long term defensibility begins.

Part VII: The Long Term

28. Programmable organizations

Today: organization → people → departments → processes → work. The future we are building toward: objective → capabilities → resources → organization → execution → outcome → organizational transition. The organization becomes dynamic. It can expand, shrink, reorganize, acquire capabilities, replace workers, create temporary teams, run experiments, change priorities, and respond to the market.

29. The long term intelligence layer

Eventually Cynqra answers: what organization is most likely to achieve this objective under these constraints? That requires accumulated knowledge of objectives, company states, organizations, capabilities, workers, intelligence, resources, decisions, interventions, and outcomes.

30. What becomes defensible

The moat is not the number of AI workers, models, or integrations. Those become commodities. The deeper asset is the accumulated record of **Objective → Company State → Organization → Decision → Intervention → Outcome → New State**. At sufficient scale, Cynqra understands patterns in organizational change. That is the long term opportunity.

One honest note: this claim sits next to the data ownership promise in §20. How cross company learning works while founders own their data is an open question for us, tracked in the Book 4 Decision Log.

Glossary

Term	Meaning
Objective	What the founder wants to achieve, in structured form
Desired State	What success looks like
Current State	Where the company actually is now
Gap	The difference between desired and current state
Company Genome	What must be true for the objective to succeed
World Model	Everything Cynqra knows about the company's reality
Capability	An ability the work requires, independent of who or what provides it
Worker	An organizational entity with identity, role, memory, authority
Intelligence Source	The underlying intelligence behind a worker (model, human, system)
Organizational Graph	The machine readable map of ownership, dependency, authority
Protocol	A structured coordination event (blocker, escalation, handoff)
Authority	What a worker is explicitly allowed to do
Verification	Proof that a task is correct, not merely completed
Evidence	The reason Cynqra believes something
Transition	A deliberate organizational change
Transition Record	The permanent account of a transition and its result
Company Memory	The full history of the organization
Event	A permanent record of a meaningful change
Founder Intervention	A unit of founder attention. The metric Cynqra minimizes

Term	Meaning
Progressive Autonomy	Earning expanded authority through demonstrated reliability

Change policy

- This book changes rarely, and only by founder decision recorded in the Book 4 Decision Log.
- If any book contradicts this one, that book is wrong, unless the founder explicitly changes doctrine.
- Version history: v1.0. Rewritten from "Cynqra Final PRD v1.0". Reorganized into seven parts, duplicates merged, glossary added, open questions flagged.
